

# 1.3 Wave Optics

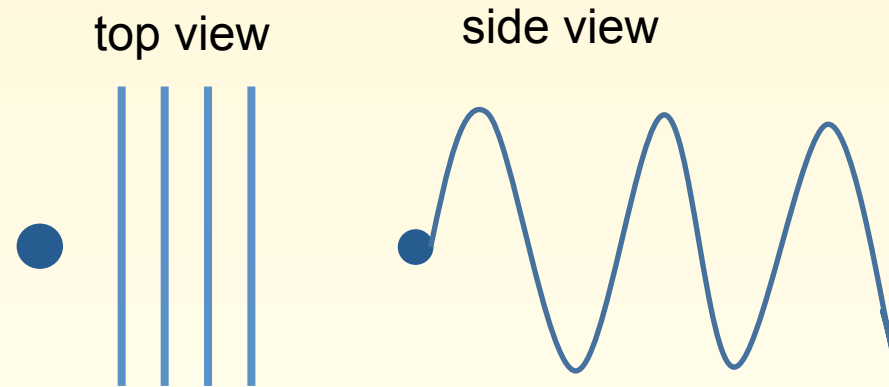

# 1.3. Wave Optics

## Light as a wave

Already in the 17<sup>th</sup> century Christiaan Huygens, a dutch physicist, proposed that light consists of waves (similiar to sound waves).

In the 19<sup>th</sup> century, the physicist James Clerk Maxwell supported Huygens theory by proposing that light is travelling as an electromagnetic wave.

# 1.3. Wave optics - Wave

## Important properties

$$\text{speed } c = \lambda \cdot f$$

$$\text{speed } c_n \text{ in medium } c_n = \lambda/n \cdot f$$

## 1.3. Wave optics - Wave

The **phase** of a wave determines the positioning of the peaks and troughs at a given time point.

**in phase**

**out of phase**

phase shift  $\alpha$   
or given in parts of  $\lambda$   
(e.g.  $\alpha$  is about  $\lambda/3$ )

# 1.3. Wave optics - Interference

Waves can interfere (adding together): amplitude of the **resulting wave** depends on the phase relation of the interfering waves

**constructive interference -**  
peaks correspond  
(phase shift is  $0$  or  $\lambda$ )

**destructive interference -**  
peaks and troughs  
(phase shift is  $\lambda/2$  or  $3\lambda/2$ )

## 1.3. Wave Optics

Regular, ordered, repetitive structures give nice interference effects.  
For example when looking through a grid, a sieve, a mesh ...
